

ABSTRACT

An imaging system includes a destination selection control to select a destination for scan data generated from an image. A software or firmware component determines a scan resolution for the scan data corresponding to a data type associated with the selected destination, and an imaging device, such as an automatic document feed scanning device, or an imaging unit in an imaging device, generates the scan data with the scan resolution. The imaging system can also include a resolution selection control to select a destination resolution. The software or firmware component determines a scan resolution that is different than the destination resolution, and generates the scan data with the different scan resolution.
